

Drone demo guide

In this tutorial, we will describe the deployment and execution of a drone demo in the Nalej Platform (v0.5.1).

You will create an architecture with development and production backend instances and deploy a drone in each of them. Then, when everything is going smoothly, you will move the drone in the development backend to the production one. The steps to do so are:

1. Create 2 Device Groups.
2. Deploy 2 DroneBackendES instances (DevelopmentBackend and ProductionBackend).
3. Configure the Kibana Dashboard for each DroneBackendES, so we can display the information sent by the drones.
4. Deploy 2 DroneBackendLocal instances (each associated to a DroneBackendES instance and to a Device Group).
5. Deploy 2 Virtual-Drone instances (each associated to a Device Group).
6. Change the connection from the DevelopmentBackend to the ProductionBackend to have both drones there.

Prerequisites

We assume that no other applications are deployed in the demo environment.

This demo requires three descriptors:

- DroneBackendES
- DroneBackendLocal
- Virtual-Drone

You can find them in the example apps repository (<https://github.com/nalej/example-apps/tree/master/components/drone-demo>). Please, upload them to the Nalej Platform but do not deploy any instances yet (you will be prompted to do so during the tutorial).

Name	In
DroneBackendLocal	
app: drone	+
Virtual-Drone	
app: drone	+
DroneBackendES	
app: drone	+

There are two variables that are also needed from your demo environment:

- **Platform:** the URI of the environment without the prefix (e.g. release051.nalej.io)
- **Organization ID:** the UUID for the demo organization (e.g. b9114109-13fd-41c3-9189-f96066ecb0c6).

The engineering team will provide you with this information in case you don't know it already.

You will also need the configuration for the default dashboard in Kibana, which is defined in a JSON file that can be found in the example apps repository: https://github.com/nalej/example-apps/blob/master/components/drone-demo/kibana_dashboard.json

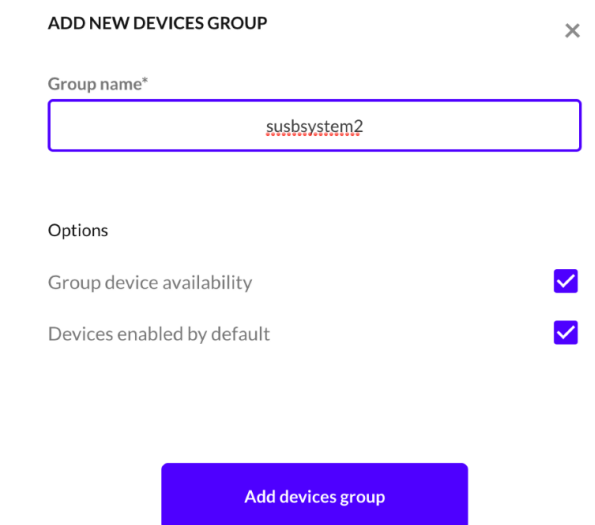

1. Creating the Device Groups

This demo requires two Device Groups, named “subsystem1” and “subsystem2”.

To create a new device group, you must go to the Devices section, and then click the “Add group” button.

A dialog like this one will appear, where you can introduce the name of the Device Group and establish the availability of the devices in this group and if they are enabled by default (please check both options).

A screenshot of a modal dialog titled "ADD NEW DEVICES GROUP" with a close button (X) in the top right corner. The dialog contains a text input field labeled "Group name*" with the text "subsystem2" entered. Below the input field, under the heading "Options", there are two checkboxes: "Group device availability" and "Devices enabled by default", both of which are checked with blue checkmarks. At the bottom of the dialog is a large blue button labeled "Add devices group".

Once the device groups have been created, they have several parameters that define them in the system. These parameters are:

- Device Group name (this is the name you chose).
- Device Group ID.
- Device Group API key.

You can access this information by clicking on the three dots that appear beside each Device Group in the list. As you can see in the image below, the Device Group ID is displayed under the Device Group name.

DEVICE GROUP INFO

SUSBSYSTEM2

5cf6dac7-715d-4170-8efc-44e30ee68f72

Device group API Key	90a3640d-0276-4d78-aa7a-95ae75535940
Default connectivity	<input checked="" type="checkbox"/>
Enablement	<input checked="" type="checkbox"/>

Close

Once you know the parameters of both Device Groups, please create a file that contains all this information, with the following structure:

```
platform:  
release051.nalej.io  
OrganizationID:  
b9114109-13fd-41c3-9189-f96066ecb0c6  
deviceGroupName:  
subsystem1  
deviceGroupID:  
98a389b4-f651-4aa8-9696-ad15c64bbcd3  
Device group API Key  
7f727c31-730a-4524-b296-fc537ee1493a
```

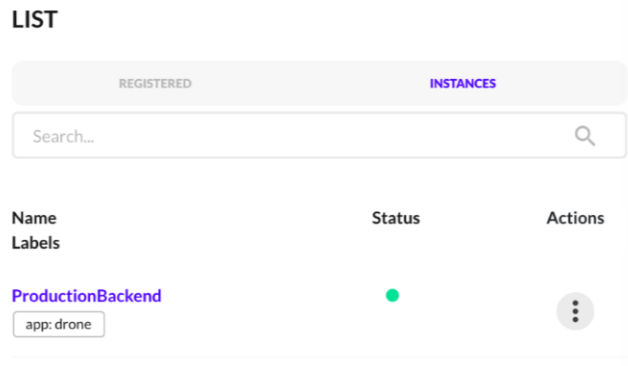

```
platform:  
release051.nalej.io  
OrganizationID:  
b9114109-13fd-41c3-9189-f96066ecb0c6  
deviceGroupName:  
subsystem2  
deviceGroupID:  
a7d76c0c-0505-4b2d-ae8e-3605074cb332  
Device group API Key  
0dc41ad6-9ea4-4d4b-9171-298af7a9da3d
```

2. Deploying backend applications

Now you need to deploy two instances of the application DroneBackendES. One of them will be called ProductionBackend and the other will be DevelopmentBackend.

When both applications are deployed, you must go to the Kibana dashboard and configure them. So, for each instance, you must follow these steps:

1. Click on the application instance in the list.

2. Go to the detailed view.

3. Click on the URL that appears in the Kibana service section.

4. Now, once in Kibana, you must load the default dashboard. Go to the section "Management>Save Objects" and click on "Import". Load the JSON file you downloaded at the beginning of the tutorial (named kibana_dashboard.json). This will include eight new objects:

Saved Objects

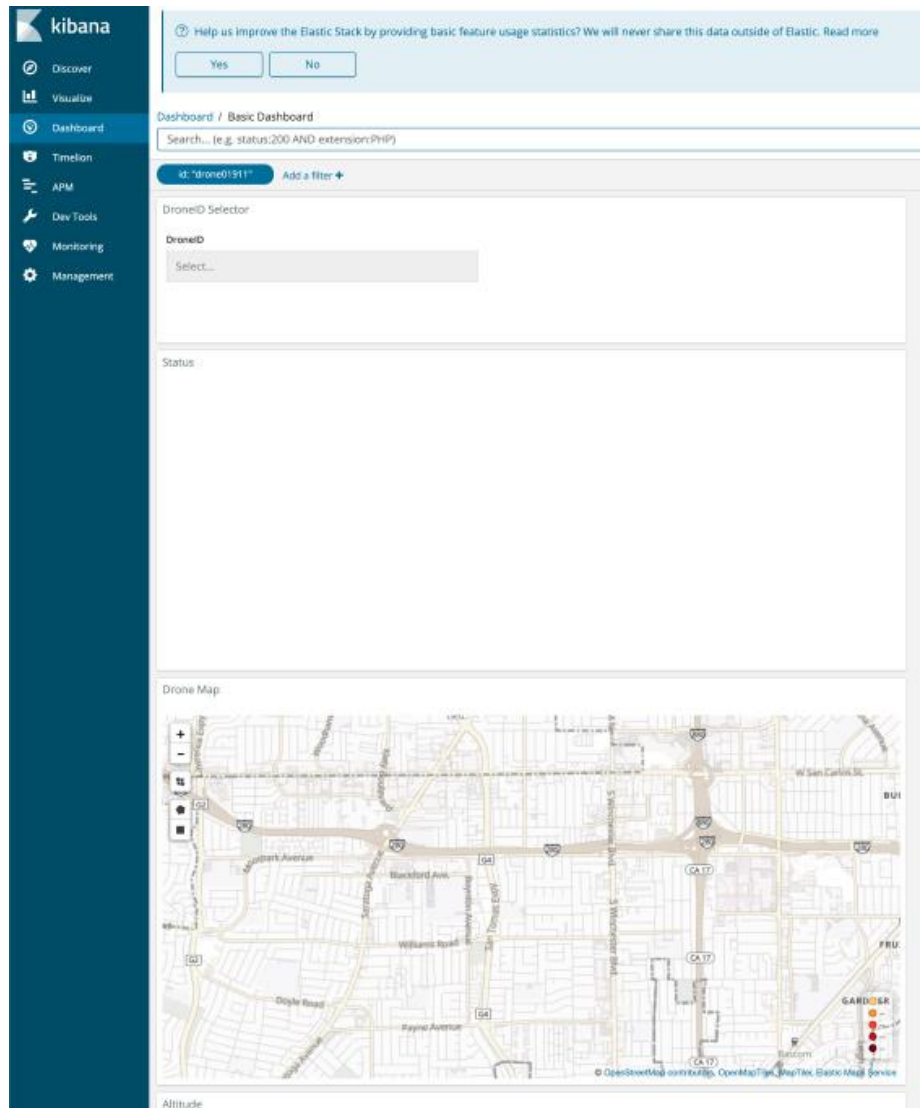

[Export 8 objects](#) [Import](#) [Refresh](#)

From here you can delete saved objects, such as saved searches. You can also edit the raw data of saved objects. Typically objects are only modified via their associated application, which is probably what you should use instead of this screen.

<input type="text" value="Search..."/>	Type ▾	Delete	Export
<input type="checkbox"/>	Type	Title	Actions
<input type="checkbox"/>		Basic Dashboard	
<input type="checkbox"/>		drone-messages	
<input type="checkbox"/>		DroneID Selector	
<input type="checkbox"/>		Drone Map	
<input type="checkbox"/>		Altitude	
<input type="checkbox"/>		Table	
<input type="checkbox"/>		Fuel	
<input type="checkbox"/>		Status	

Rows per page: 20 ▾

5. Now, when you go to the section Dashboard>Basic Dashboard, you can view it deployed.
Remove the quick filters and configure the auto-refresh to get the view to update automatically.

Remember to follow these steps for both DroneBackEnd instances.

3. Deploying local applications

After deploying the Development and Production backend applications, you need to deploy the two DroneBackendLocal applications. These are named LocalSystem1 and LocalSystem2, and are configured as follows:

- LocalSystem1 is connected to the Device Group subsystem1, and its target instance is ProductionBackend.
- Meanwhile, LocalSystem2 is connected to the Device Group subsystem2, and its target instance is DevelopmentBackend.

Below you have the screenshots of both deployments, so you can see where each connection is specified.

4. Deploying virtual drones

Now that you have the architecture in place, it's time to launch a virtual drone for each Device Group. Please deploy two instances of the Virtual-Drone application, called subsystem1 and subsystem2.

- Subsystem1 is linked to the Device Group subsystem1, and thus uses its deviceGroupID and deviceGroupAPIKEY.
- Subsystem2 is, as you may have guessed, linked to the Device Group subsystem2, and uses the parameters that describe it.

Retrieve the file you saved when creating the Device Groups in step 1 of this tutorial and use the information in it to configure the Virtual-Drone instances appropriately. We provide some screenshots to illustrate where to use this information below.

Now the system is live, and you can check that the drones are sending the correct data in Kibana's Dashboard.

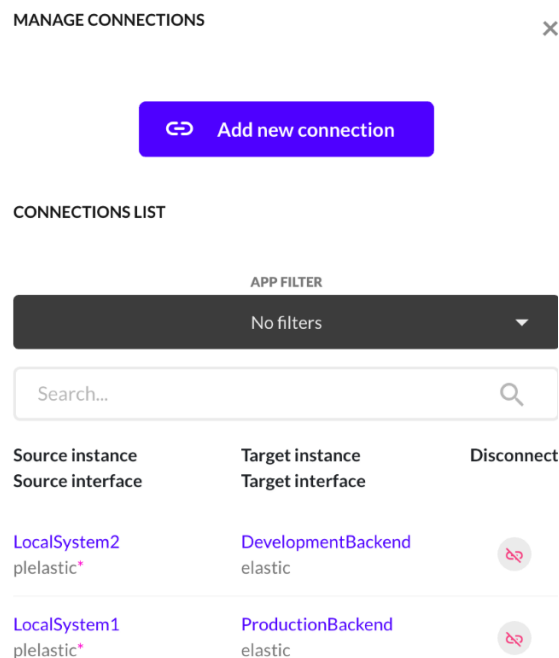

If you can't see the path the drones are following in the map, click on the third icon, and the map will focus on the area that has data to show.

5. Change the network connections

Now you need to move what was in the development backend to the production backend. You can do that by removing the application network connection between LocalSystem2 and DevelopmentBackend, and then create a new one between LocalSystem2 and ProductionBackend.

To remove the connection, click on the “Manage connections” button in the upper right corner of the Application view. Then, click Disconnect in the connection you don't want anymore (LocalSystem2 – DevelopmentBackend).

After that, you can create a new connection clicking on the instance to go to its detailed view, and adding a new connection there:

ADD NEW CONNECTION

Source instance

Target instance

Source interface

Target interface

Add new connection

And you're done! To check if everything is correctly configured, please go to Kibara's Dashboard and check that all the drones are sending data to the production backend.
